4.0 Baseline Habitat Data

Baseline habitat data is currently being compiled for salmonids in Washington. The Washington State Conservation Commission, in consultation with local government and treaty tribes, is developing limiting factors reports on habitat conditions in Water Resource Inventory Areas (WRIAs) throughout the state⁴. The intent of these *Habitat Limiting Factors* reports is to help local organizations collect data and identify gaps in existing information on factors affecting natural salmonid production. The reports may be considered the environmental baseline for salmonid habitat in Washington.

This habitat data collection began under Engrossed Substitute House Bill (ESHB) 2496, which was passed by the Washington State Legislature and signed into law in 1998. The resulting law was codified in Revised Code of Washington Chapter 77.85 RCW (Salmon Recovery). Its purpose is "to identify the limiting factors for salmonids," where "limiting factors" are defined as "conditions that limit the ability of habitat to fully sustain populations of salmon." The statute further clarifies the definition by stating, "These factors are primarily fish passage barriers and degraded estuarine areas, riparian corridors, stream channels, and wetlands." Implementation of RCW 77.85 does not constitute a full limiting factors analysis. It does, however, represent Best Available Science (BAS). Hatchery, hydroelectric, and harvest segments of identified limiting factors are covered in other forums.

The Legislature directed the Commission to form Technical Advisory Groups (TAGs) to write the reports. The TAGs consist of private, federal, state, tribal, and local government personnel with appropriate expertise. To date, the TAGs have completed several *Habitat Limiting Factors* reports, which are developed on a WRIA basis. Washington State contains 62 WRIAs; 26 reports are complete; 12 are currently underway; and 24 are not yet begun. The completed *Habitat Limiting Factors* reports are located in Appendix A of this BR. Appendix A is a separately bound volume.⁵

4.1 WRIA Based Data

For the *Habitat Limiting Factors reports*, each WRIA is subdivided into separate watersheds or sub-basins. Each chapter presents data on habitat-limiting factors for each watershed or sub-basin. Following are examples of limiting factors:

- Watershed characteristics and conditions (location, topography, climate, hydrology, geology and groundwater movement, soils and vegetation)
- Historic and current land use

• Access to spawning and rearing habitat

• Floodplains and channel conditions

⁴ Water Resource Inventory Areas were established in the early 1970s by the state of Washington for the purpose resource planning and management. A WRIA is essentially an administrative unit that closely follows watershed boundaries. There are 62 WRIAs is Washington state (WAC 173-500-040).

⁵ Contact the Washington State Conservation Commission for full text copies of these reports. Maps included in the reports were created and will be updated by the Commission.

- Riparian conditions
- Water quality
- Exotic and opportunist species
- Biological processes
- Estuarine and nearshore habitat.

Table 21, summarizes the specific known habitat limiting factors in each WRIAs in Washington state (i.e., the environmental baseline). Baseline data includes such information as location, subbasins, land use, zoning, nearshore habitat and forage fish, known and presumed distribution of aquatic species, barriers, structural elements, channel characteristics, water quality, instream flow, riparian condition, watershed health and other data.

This WRIA-based data is drawn from the following sources:

- Formal habitat inventories or studies specifically directed at evaluating fish habitat.
- Other watershed data not specifically associated with fish habitat evaluation.
- Personal experiences and observations of watershed experts involved in the TAGs.

Few, if any, of the habitat data or observations meet the highest standard of peer review literature. However, they should nevertheless be considered presumptively valid because they are based on the experiences of the watershed experts actively working within these areas. Future peer review and research of data gaps will require additional watershed research or evaluation by the Commission.

4.2 Findings on Salmonid Habitat in Washington State

Although the data was scattered, and the specific habitat concerns differed among WRIAs and streams within the WRIAs, some common habitat findings emerge:

- Adjacent land management practices and direct actions within stream corridors have significantly altered natural stream ecological processes.
- Fine sediment (.85 mm) levels in stream gravels regularly exceed the <12% level identified as representing suitable spawning habitat (USFWS 1999).
- Lack of adequate LWD in streams, particularly larger key pieces needed to develop pools, log jams, and other habitat components important to salmonids.
- Lack of adequate pools, and large, deep pools important to rearing juvenile salmonids and supporting adult salmonids during their upstream migrations.
- Naturally high rates of channel constrictions, which further worsens the rate of streambank erosion and substrate instability due to loss of streambank and riparian integrity, and the alteration of natural hydrology.
- Loss of riparian function due to removal, or alteration, of natural riparian vegetation. This habitat loss affects water quality, lateral erosion, streambank stability, and instream habitat conditions.

- Presence of a significant number of barriers, such as culverts, screens, water diversions, and dams. Barriers prevent unrestricted upstream and downstream access to juvenile and adult salmonids.
- Significant alterations to natural stream hydrology in streams where uplands have been heavily developed. The threat of similar impacts to streams experiencing current and future development growth.
- Physical alteration of the natural estuary has significantly impacted estuarine/marine function. For example, bulkheads may cause poor water quality and significantly alter nearshore ecological function.

The *Habitat Limiting Factors* reports provide environmental baseline information that can, and should, be used to develop salmonid habitat protection and restoration strategies. The Regional Program supports these strategies by developing BMPs that avoid and minimize impacts to aquatic habitats due to routine road maintenance activities.

It is not the intent of this BR, nor the Regional Program, to duplicate the Commission's work, but to help make the *Habitat Limiting Factors* reports available to state and local governments' environmental and road maintenance staff. Additional habitat assessment data and habitat restorations are incorporated into the Commission's existing documents, and therefore are considered to be living documents. The Regional Program Element 8: Adaptive Management (through the Regional Forum) allows this material to be passed on to state and local road maintenance agencies for use at their discretion.
